Abstract

As two important constituents of China's macro economy, there are a variety of relationships among China's stock market, real estate market and its macro economy. In order to investigate these relationships, in this paper, especially with the Macroeconomic Boom Index reflecting China's macro economy, we use cointegration theory and Granger analysis to demonstrate that there are long-term equilibrium relationship and bidirectional causality between the macro economy and the securities business, also between the macro economy and the real estate market, however, this kind of long-term Equilibrium relationship and bidirectional causality appears very weak.

Keywords: Macroeconomy; Stock Market; Real Estate Market; Linkage; Cointegration; Granger Causality Test

1. Introduction

Many scholars have researched the correlation among macroeconomy, security market and real estate market. Among them, Bharat and Zan(2002) studied the relationship between the real estate prices and national incomes in Sweden and U.K. and their results showed that Swedish national income induced real estate price's fluctuation while there was causality between British national income and housing price. Tsatsaronis and Zhu(2004), by constructing VAR model comprising actual housing price, CPI, GDP and short-term interest rate, decided that the real estate price was mostly effected by inflation while weakly effected by national income. Iacoviello and Minetti(2006) researched the influence of real estate on macroeconomic fluctuation and concluded that the change of real estate price significantly activated national consumption. Demary(2009) studied ten OCED countries' correlation among their housing price, inflation rate and interest rate, and found that the macroeconomy heavily effected the real estate price. George et al(2005) constructed VAR model and VEC model and studied the relationship between Germanic stock market and macroeconomy, the research result demonstrated that the flourishing stock market could accelerate the development of macroeconomy. Nieuwerburgh et al(2006) analyzed the relationship between Belgium's stock market and macroeconomy and realized that the stock market might discriminatively boost economic growth at different stage, i.e., there are different relationships between stock market and macroeconomy under different circumstances. Muhammad S. et al(2008) studied how Pakistan's stock market influenced its macroeconomic development at long-term and at short-term, respectively, they acquired results as there existed mutual causality between stock market and macroeconomy in the long run while only unidirectional influence from the former to the latter in the short run. Similarly, Enisan et al(2009) tested the causality between African stock markets and macroeconomy based on VEC

model and cointegration test.

In this paper, by using of Granger causality test method and relying on VAR and VEC model while with macroeconomic climate index reflecting China's macroeconomy situation, we study the correlation among China's macroeconomy, stock market and real estate market. Our research includes whether there is long-term equilibrium relationship or short-term correlation among aforementioned three markets; whether and how the fluctuation of macroeconomy cause real estate's and stock market's change; whether and how real estate's and stock market's fluctuation affect macroeconomic situation. Our findings indicate that there are long-term equilibrium relationship and bidirectional causality between the macroeconomy and the securities business, also between the macroeconomy and the real estate market, however, this kind of extended Equilibrium relationship and bidirectional causality appears very weak.

The rest of paper is organized as follows. In section 2, the basic variables and model are introduced. Section 3 considers how to select sample data, in section 4, empirical analysis is conducted to demonstrate the relationship among china's macroeconomy, stock market and real estate market, while the last section concludes.

2. Variable and Model

2.1. Selection of variable

When select variable, we usually take its economic signification into account besides the possibility to collect corresponding data. In this paper, we mostly study the linkage among china's macroeconomy, stock market and real estate market, thus, we select macroeconomic climate index to reflect situation of China's macroeconomy, while choosing Shanghai Composite Index and Real Estate Climate Index scaling China's stock market real estate market, respectively.

2.2. Basic model

As to multidimensional time serial $y_t = (y_{1t}, \dots, y_{kt})$

- Call $y_t \sim CI(d, b)$, if $y_{it} \sim I(d)$, $i = 1, \dots, k$ and $\beta' y_t \sim I(d - b)$ with nonzero vector β .
- Call expression (1) as a VAR(p) model,

$$y_t = A_1 y_{t-1} + \dots + A_p y_{t-p} + U_t \quad (1)$$

Where y_{it} , $i = 1, \dots, k$ denote nonstationary $I(1)$ variables; A_j , $j = 1, \dots, p$, k -rank parameter matrix; and

U_t , k -dimension error vector.

When denote $\Pi = \sum_{i=1}^p A_i - I$, which is called compressed matrix, and $\Gamma_i = -\sum_{j=i+1}^p A_j$ ($i = 1, \dots, p-1$), we can

make difference to (1) and get

$$\Delta y_t = \Pi y_{t-1} + \sum_{i=1}^{p-1} \Gamma_i \Delta y_{t-i} + U_t \quad (2)$$

As a result of assuming $y_t \sim I(1)$, thus, $\Delta y_t \sim I(0)$. In (2), all terms, with except of Πy_{t-1} , are stationary. So, there is not cointegration among all components of y_t when Πy_{t-1} being nonstationary, and vice versa. Suppose $rank(\Pi) = r$, which indicates there being r cointegrations, then, Π can be decomposed into $\Pi = \alpha\beta'$, where α, β are $k \times r$ rank matrices and $rank(\alpha) = rank(\beta) = r$. Let $vecm_{t-1} := \beta' y_{t-1}$ as error correct term, there is

$$\Delta y_t = \alpha vecm_{t-1} + \sum_{i=1}^{p-1} \Gamma_i \Delta y_{t-i} + U_t \quad (3)$$

(3) is called a error correct model of a cointegration system. $vecm_{t-1} := \beta' y_{t-1}$ reflects equilibria relationship of system in the long run.

3. Data

Take acquirability and synchronization into account, In this paper, we select monthly historic data of national real estate climate index from January, 1999 through September, 2012 to reflect real estate market while selecting homochronous Shanghai Securities Complex Index and macroeconomic climate index to reflect china's stock market and macroeconomic situation, respectively. In order to eliminate influence of seasonal factor and heteroskedasticity, we first adjust all original data with X12 method and make logarithmic operation, signing as $\ln(RECI)$, $\ln(SHCI)$ and $\ln(MECI)$. Seeing figure 1.

Seeing from figure 1, we can know that china's macroeconomy, stock market and real estate market run equilibriumly in the long run, however, there are deviation instances in the short run.

Fig 1 Trend of Macroeconomic Climate Index, Shanghai Securities Complex Index and National Real Estate Climate Index

4. Empirical Specification

4.1 Stationarity testing

In order to avoid fallacious regression, empirical analysis demands time series being stationary, and ADF testing is a conventional method to test stationarity of time series. From figure 1, it's difficulty to decide whether three time series are of marked trend, here, we verify the stationarity with following models in turn.

If there seems existing constant term and trend term in time series, the testing model can be

$$\Delta y_t = \alpha + \beta t + \delta y_{t-1} + \sum_{j=1}^p \lambda_j \Delta y_{t-j} + u_t \quad (4)$$

If there seems being no trend term but being nonzero mean value, the testing model will be

$$\Delta y_t = \alpha + \delta y_{t-1} + \sum_{j=1}^p \lambda_j \Delta y_{t-j} + u_t \quad (5)$$

Else if there seems being no trend term and no constant term and the time series is fluctuating around zero, the testing model can be

$$\Delta y_t = \delta y_{t-1} + \sum_{j=1}^p \lambda_j \Delta y_{t-j} + u_t \quad (6)$$

In ADF testing, the number of lagging terms may be ascertained by AIC criterion or SIC criterion, here, we select number of lagging terms to be 2 and do unit root test with software Eviews. The testing results are showed in table 1 as following.

As seen in table 1, three logarithmic time series are not stationary but the differenced time series of them are stationary, i.e., $\ln(\text{MECI})$, $\ln(\text{SHCI})$ and $\ln(\text{RECI})$ are $I(1)$ time series, we can do cointegration testing for them.

Table 1 Unit Root Testing

	ADF value			Stationarity
	Model(4)	Model(5)	Model(6)	
Ln(MECI)	-3.102152	-3.467285	0.386566	NO
Ln(SHCI)	-1.562866	-1.769621	-0.105709	NO
Ln(RECI)	-1.745272	-1.468392	-0.362758	NO
dLn(MECI)	-10.08320***	-9.921276***	-9.933355***	YES
dLn(SHCI)	-7.139804***	-7.108832***	-7.113474***	YES
dLn(RECI)	-9.099092***	-8.937749***	-8.955171***	YES

Note: d denoting 1-rank difference; ***, ** and * denoting being significant at significance level 1%,5% and 10%, respectively

4.2 Cointegration Testing

Now, we respectively use Johansen testing method and EG testing method to test the cointegration relationship among $\ln(\text{MECI})$, $\ln(\text{SHCI})$ and $\ln(\text{RECI})$. The results are just as in table 2 and table 3. firstly, the testing results of two kinds of method are consistent, then, we can decide that there exists cointegration relationship between $\ln(\text{MECI})$ and $\ln(\text{RECI})$ and between $\ln(\text{MECI})$ and $\ln(\text{SHCI})$, but there does not exist cointegration relationship between $\ln(\text{SHCI})$ and $\ln(\text{RECI})$. By this token, in China, the macroeconomy is keep long-term equilibrium relationship with stock market and so does between macroeconomy and real estate market, which is in accord with other scholars' results, however, there is not obvious equilibrium relationship between China's stock market and real estate market.

Table 2 Johansen Cointegration Testing

	Hypothesized No. of CE(s)	Trace Statistic	Max-Eigen Statistic
$\ln(\text{MECI})$ & $\ln(\text{SHCI})$	None *	19.04725(15.49471)[0.0139]	15.21074(14.26460)[0.0353]
	At most 1	3.836511(3.841466)[0.0501]	3.836511(3.841466)[0.0501]
$\ln(\text{MECI})$ & $\ln(\text{RECI})$	None *	18.53170(15.49471)[0.0169]	14.83535(14.26460)[0.0406]
	At most 1	3.696352(3.841466)[0.0545]	3.696352(3.841466)[0.0545]
$\ln(\text{RECI})$ & $\ln(\text{SHCI})$	None	13.03136(15.49471)[0.1137]	11.97331(14.26460)[0.1117]
	At most 1	1.058052(3.841466)[0.3037]	1.058052(3.841466)[0.3037]

* denotes rejection of the hypothesis at the 0.05 level; () denotes 0.05 critical value; [] denotes P value

Table 3 EG Cointegration Testing

	ADF of residual error time series	t-statistic	Stationarity of residual error time series
$\ln(\text{MECI})$ & $\ln(\text{SHCI})$	-2.05192	-1.94287	YES
$\ln(\text{MECI})$ & $\ln(\text{RECI})$	-2.22173	-1.94278	YES
$\ln(\text{SHCI})$ & $\ln(\text{RECI})$	-1.72279	-1.94278	NO

4.3 Granger Causality Testing

By Grange expression theorem, if there exists cointegration between variables, there is at least one grange causality from one variable to the other. So, according to the preceding results, it is necessary for us to judge the causality among $\ln(\text{MECI})$, $\ln(\text{RECI})$ and $\ln(\text{SHCI})$.

However, the Grange Causality Testing is aim at stationary time series, so, we first make difference operation to time series $\ln(\text{MECI})$, $\ln(\text{RECI})$ and $\ln(\text{SHCI})$, respectively. The results of grange causality testing are showed in table 4, from which, we can see that it is real that there is bidirectional granger causality between China's macroeconomy and stoch market under significant level 5%, and so does between China's macroeconomy and real estate market, which is true to economical common sense.

Table 4 Granger Causality Testing

Null Hypothesis:	Obs	F-Statistic	Prob.	conclusion
D(LNRECI) does not Granger Cause D(LNMECI)	161	3.74737	0.0124	Reject
D(LNMECI) does not Granger Cause D(LNRECI)		3.08733	0.0290	Reject
D(LNSHCI) does not Granger Cause D(LNMECI)	161	3.34890	0.0117	Reject
D(LNMECI) does not Granger Cause D(LNSHCI)		2.88897	0.0243	Reject
D(LNSHCI) does not Granger Cause D(LNRECI)	161	3.19267	0.0253	Reject
D(LNRECI) does not Granger Cause D(LNSHCI)		1.68350	0.1729	No rejecting

Note:according to AIC criterion, here, the number of lagging terms is 3.

5.Conclusion and Further Research

In this paper, we have investigated the correlationship among China's macroeconomy, stock market and real estate market and conclusions as following can be concluded

Generally speaking, China's macroeconomy keeps long-term equilibrium and bidirectional causality with the stock market, however, because of the juvenility of China's securities market, both of China's macroeconomy and stock market only weakly influence each other, this kind of feeble interaction demonstrates that China's securities market, as a component of China's macroeconomy, does not exhibit its proper function to the latter. So, as a conclusion, China ought to enlarge its stock market's scale, transform its government functions that intervene too much to stock market's development, and in China, investors should more reasoningly invest instead of taking a risk.

Similarly, we also find there exists a long-term equilibrium relationship and bidirectional causality between China's macroeconomy and real estate market. In fact, on the one hand, development of China's real estate market has become an important constitute of its macroeconomy, however, on the other hand, for Chinese government, it shall be alert to excessively rely on real estate to accelerate macroeconomic development, or else real estate bubble may come into being. Hence, Chinese government should properly regulate the real estate market and control it in its correct development orbit.

However, our research indicates that no obvious long-term equilibrium or causality exists between China's stock market and real estate market, which tells us that, in China, these two financial markets can not effectively substitute each other, In addition, adjustment of china's dummy economy will not arouse change in substantiality economy. So, we must synchronously boost two markets,only in this way, China's macroeconomy can truely boom.

Lastly, in this paper, we only investigated the correlationship among China's macroeconomy, stock market and real eateate market, and we did not construct quantitative model to scale this kind of correlationship, which is our further study in this domain.
